Introduction

The main goal of the project was to create a program capable of intercepting packets on the network and printing them in a special format.

A packet sniffer — also known as a packet analyzer, protocol analyzer or network analyzer — is a piece of hardware or software used to monitor network traffic. Sniffers work by examining streams of data packets that flow between computers on a network as well as between networked computers and the larger Internet.

Usage

Build the program with:

make

Run the program:

```
sudo ./ipk-sniffer [-i interface | --interface interface] {-p port} {[--tcp|-t] [--udp|-u] [--arp] [--icmp] } {-n num}
```

The program needs root access to the interface to be capable of reading the packets.

The arguments can be in any order.

- <u>interface</u> says what interface should the program use for sniffing. If the argument -*i* is omitted, then the program prints out the available interfaces.
- port filters the packets depending on the given port number. If not specified, all ports are considered.

- <u>num</u> states how many packets we wish to be printed out. If not specified, consider displaying only one packet.
- if -t or --tcp outputs only TCP packets.
- if -u or --udp outputs only UDP packets.
- if --icmp outputs only ICMPv4 and ICMPv6 packets
- if --arp outputs only ARP frames

If specific protocols are not specified, they are all considered for printing.

Example:

```
sudo ./ipk-sniffer -i eth0 -p 23 --tcp -n 2
sudo ./ipk-sniffer -i eth0 --udp
sudo ./ipk-sniffer -i eth0 -n 10
sudo ./ipk-sniffer -i
```

Implementation

The sniffer is written in C language with additional libraries like <u>pcap.h</u> and others.

Two structures have been developed. *Packet* is used to store information about packets. Structure *Arguments* is used to correctly process options entered by the user.

First, the *handle_args* function takes command line arguments and fills the structure with the *arguments*. For arguments with optional parameters, I used the macro OPTIONAL_ARGUMENT_IS_PRESENT, which I was inspired by on this <u>page</u>. This makes the code more readable and helps save an optional argument parameter, if present.

Next, it was necessary to get a list with all available interfaces for further connection. The *pcap_findalldevs* function helped me with this. After that we need to get interface source IP and netmask using *pcap_lookupnet*. Otherwise, an error will be printed and the program will exit with number 1.

The *pcap_open_live function* will then open the interface for sniffing and *handle_protocols* will start processing the protocols entered by the user, if requested. Next, the *pcap_compile* compiles protocols into a filter program. And already *pcap_setfilter* sets the necessary protocol filters.

After that, the program starts sniffing the requested interface thanks to the *pcap_loop* function. And the *got_packet* is a call back function that parses each captured packet. It initializes the *Packet* structure, defines the <u>protocol</u> and calls the appropriate function to set the header data.

handle arp - Stores the source and destination IP address (Address Resolution Protocol).

Functions *handle_ip* and *handle_ipv6* work with Internet Protocol and Internet Protocol version 6, respectively. The *inet_ntop* function helps process addresses and store them.

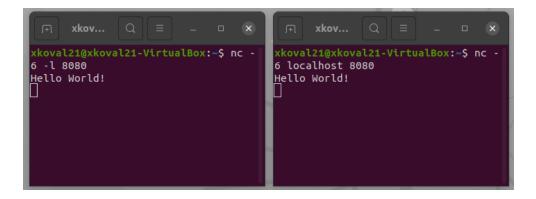

After the header data is filled in, the program prepares the time in a special format for timestamp and, using the two functions <code>handle_packet</code> and <code>handle_hex_dump</code>, displays information about the packet. Finally, <code>pcap_freecode</code> releases the specified allocated memory, and <code>pcap_close</code> closes the files associated with the packet capture channel.

Testing

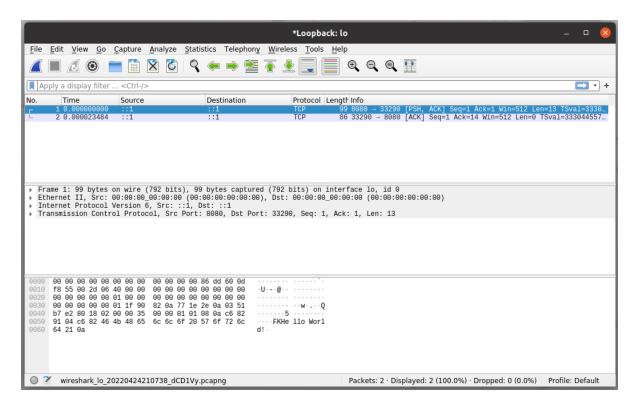

Tested with a VirtualBox virtual machine. On Ubuntu version 22.04 using the Wireshark traffic analyzer.

Transmission Control Protocol

Two terminals were used for testing. Two terminals were used for testing. The first terminal used the *nc* -6 -*l* 8080 command. And in the second terminal *nc* -6 localhost 8080. 8080 is a port, so we can check that the -p operator works correctly. Now we send the text to the terminal and it is displayed in another terminal. This means that the package has been sent.

In Wireshark, through the lo interface, we can see two packets that have been sent:

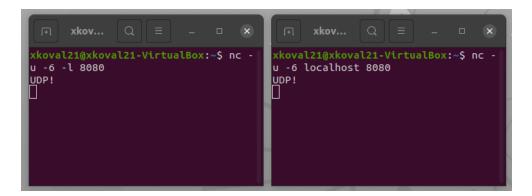

Compare this with the data from the ipk-sniffer program:

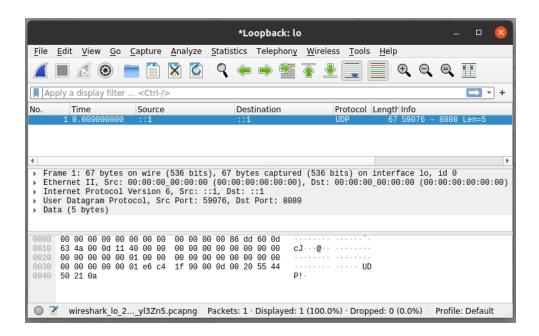

```
xkoval21@xkoval21-VirtualBox: ~/Desktop/ipk
koval21@xkoval21-VirtualBox:~/Desktop/ipk$ sudo ./ipk-sniffer -i lo -t -p 8080،
[sudo] password for xkoval21:
